

Type 1 Diabetes

Our bodies need fuel for proper function. **Glucose** (sugar) is the fuel that our cells use to produce energy. In order to process the sugar we eat in various foods, our bodies produce **insulin**. Insulin is a hormone made by **beta cells**, clusters of cells in the pancreas (an organ located in the upper abdomen).

In **type 1 diabetes**, the beta cells in the pancreas are unable to make insulin because of **autoimmune** disease. This means that the body's immune system makes **autoantibodies** that attack and destroy the pancreatic beta cells. **Type 2 diabetes** is the result of the body's inability to properly use the insulin made by the pancreas and almost always occurs in adults and children who are overweight. Because type 1 diabetes usually starts in childhood, it is sometimes called **juvenile diabetes**. Type 1 diabetes is a serious illness that cannot be cured, but it can be treated and controlled. The September 26, 2007, issue of *JAMA* includes an article about children at risk for type 1 diabetes. This Patient Page is based on one previously published in the October 22/29, 2003, issue of *JAMA*.

CHARACTERISTICS OF UNTREATED TYPE 1 DIABETES

- Thirst
- Frequent urination
- Weight loss
- Poor infant growth
- High blood glucose level

COMPLICATIONS OF TYPE 1 DIABETES

- **Diabetic ketoacidosis**—a life-threatening medical condition, also known as diabetic coma, caused by the body's need to break down fats for energy instead of using sugars
- Kidney failure
- Diabetic **retinopathy**—damage to the retina of the eye
- **Gastroparesis**—the stomach does not empty properly, allowing partially digested food to accumulate
- Diabetic **neuropathy**—loss of sensation and nerve control of body functions
- Increased occurrence of infections
- Poor circulation, especially in the feet and legs
- Coronary heart disease

MANAGEMENT OF TYPE 1 DIABETES

- Insulin injections or an insulin pump—oral medications do not work
- Diet
- Exercise
- Frequent checks of blood glucose levels
- Management of other medical problems including high blood pressure and coronary heart disease
- Screening for and early recognition of diabetes complications
- Kidney dialysis or transplantation for kidney failure
